

OOP and Exceptions

Class versus Object

- ▶ Class – A framework; the definition of the format of the “thing”
- ▶ Object – An instance of the “thing”
- ▶ Examples:
 - ▶ Blueprint / House
 - ▶ Outline / Essay
 - ▶ Cookie Cutter / Cookie

Important Reminder

Variables, in Java, are references, unless the variable is a primitive

Object class

- ▶ In Java, all classes derive from a root class, called “Object.”
- ▶ Object defines a number of functions which, obviously, all classes derive due to inheritance rules
 - ▶ clone – create a copy of the object
 - ▶ toString – similar to repr/str in Python
 - ▶ finalize – similar to destructor in C++, but less useful
 - ▶ hashCode – similar to __hash__ in python

Constructors

- ▶ You can have as many as you'd like!
 - ▶ Constructors can “invoke” other constructors with “this” calls
 - ▶ Default parameters to functions aren't possible so “this()” is going to be very useful

Operator overloading...

- ▶ ..you can't... 'nuf said

Access Specifier (protection)

- ▶ public
- ▶ private
- ▶ protected
- ▶ (default)

(default)

- ▶ Java's "default" access specifier is used if you do not specify another access specifier.
- ▶ Default (your book calls it "Package Private") is needed because of Java's heavy use of classes!
- ▶ Classes are combined into "packages" and all member methods from all classes inside a package have access to the "default" members.
- ▶ (we will cover packages later in the semester)

Static versus Instance members

- ▶ Usually we want everything stored in the object, so variables that are “instance” variables are stored as we experienced in C++; inside the object.
 - ▶ These require instantiation of the object in order to use
 - ▶ We have one per object
- ▶ Sometimes, we’d like to “share” a variable across all of the objects in a class. If a variable is made “static” it is stored inside the class
 - ▶ These DO NOT require instantiation of the object!
 - ▶ We have one copy per class
 - ▶ They can be accessed using the name of the class (preferred) or the name of any object of the class (will generate a warning)
- ▶ Functions can also be “static.” Static functions DO NOT require instantiation of the object.
 - ▶ Static functions can only access static variables!

Inheritance

- ▶ Java uses “extends” and only has public inheritance
- ▶ Java prohibits multiple inheritance
- ▶ Everything inherits from Object (the ultimate base class)

Derived calling base

- ▶ Constructors – Since the derived class can have only one base class, there is no need to “name” the Base class constructor you wish to call, it’s “super.”
- ▶ Base methods called from Derived class
 - ▶ Access specifiers still apply
 - ▶ No need to name the base class, again just use “super” i.e. `super.method(param)`
 - ▶ You cannot use `super.super!`

Abstract Classes

- ▶ Similar to C++
- ▶ An abstract class contains one or more abstract functions
- ▶ Abstract classes cannot be instantiated

Final class / final method

- ▶ (no, not our final class, this is the beginning of the semester!)
- ▶ A class marked as “final” cannot be used as a base class
- ▶ A final method cannot be overridden

Quick question

- ▶ Main exists inside of a class. How many objects of that class are instantiated?
- ▶ Follow up question – Can main ever access instance variables?

Exceptions – They're exceptional!

- ▶ Java is STRICT with exceptions!
- ▶ Exceptions must be known at compile time
- ▶ All checked exceptions must be caught
 - ▶ Unchecked exceptions include errors like `IntegerDivideByZeroException`, `ArrayIndexOutOfBoundsException` and `NullPointerException`
- ▶ If your method may “throw” an exception, it must be listed in the “throws” portion of the function signature.

Try / Throw / Catch

- ▶ Similar to C++
- ▶ For an object of a class to be thrown, it must extend Throwable (or derive from one that does, somewhere in its ancestry)
- ▶ An object is thrown and the object usually carries a “message” which can be retrieved with toString

Finally

- ▶ No, we're not done quite yet
- ▶ Finally will ALWAYS run even if there is no catch block for the data type thrown.
- ▶ Often used to “clean up” objects, but not in the memory management sense

Assertions

- ▶ “assert conditional: “conditional is not true!”
- ▶ Same as “throw AssertionError”
